Abstract

Diazirines and diaziridines are three-membered heterocycles containing two nitrogen atoms. Photolysis or thermolysis of diazirines generates carbenes; consequently, diazirines are frequently applied as easily handled and readily synthesized carbene progenitors. In this role, diazirines have been widely employed in biological systems as photoaffinity probes and as carbene precursors in surface modification research. Diaziridines have been used synthetically as aziridinating reagents and several diaziridines possess interesting biological activity. This chapter reviews developments in diazirine and diaziridine chemistry over the period 1996–2007 and encompasses modern *ab initio* theoretical studies, the application of various experimental methods to structural analysis, thermodynamic aspects, reactivity with and without ring cleavage, contemporary synthesis, and applications.
